There is a powerful electrostatic potential that exists between the chlorine dioxide molecule and a pathogen. When they encounter one another a change takes place and there is a reaction between them. In the process, the pathogen lets go of up to five up its electrons. This is a fatal blow to the pathogen and a win for the body. Once the electrons have been taken, the mms products molecule is used up as well.

It is quite harmless even with its extra electrons. It then begins to break down itself, into a harmless salt byproduct. The pathogen has been done away with and all is well.

It's an amazing process that works consistently well.
